Abstract

Although the upregulation of autotaxin (ATX) is associated with many solid tumours, its role in pancreatic neuroendocrine neoplasms (pNEN) has not been well elucidated. The expression of ATX in pNEN tissues and pNEN cell line BON1 was analysed by Western blot, PCR and immunocytochemistry upon exposure to interleukin-6 (IL-6). Additionally, pNEN cell line BON1 was transfected with siRNAs against ATX or signal transducer and activator of transcription 3 (STAT3) and assessed by *in vitro* invasion assays. The following results were obtained. The expression of ATX in pNEN tissues was significantly increased compared with that in normal pancreatic tissues. High ATX expression was strongly correlated with tumour grade, lymph node metastasis and tumour-node-metastasis stage. Furthermore, ATX downregulation notably inhibited the metastatic capacity of pNEN cells, whereas STAT3 knockdown was found to downregulate the expression of ATX. ATX expression was upregulated in BON1 cells upon stimulation with IL-6, and this was accompanied by activation/phosphorylation of STAT3. Western blot analysis of human pNEN tissue extracts confirmed increased ATX expression and STAT3 phosphorylation with elevated expression levels of IL-6. In conclusion, ATX is upregulated in pNEN and is correlated with the metastatic capacity of pNEN cells, potentially via interaction with STAT3 activation.

Introduction

The incidence of pancreatic neuroendocrine neoplasm (pNEN), the most aggressive neuroendocrine malignancy among gastroenteropancreatic neuroendocrine neoplasms (GEP-NENs), has increased significantly over the past few decades, with the incidence rate increasing approximately 4.6-fold from 1973 (0.18 per 100,000) to 2012 (0.82 per 100,000) in the United States (1, 2, 3). PNEN is a clinically rare and heterogeneous disease of the pancreas with variable clinical presentation that depends on histological features and disease staging, resulting in widely variable prognoses for different pNENs (4). Therefore, there is

a critical need to better define the molecular features associated with prognosis in these tumours.

Autotaxin (ATX), or nucleotide pyrophosphatase-phosphodiesterase 2 (ENPP2), is a secreted glycoprotein with lysophospholipase D activity that primarily catalyses the hydrolysis of lysophosphatidylcholine, resulting in lysophosphatidic acid (LPA) production (5, 6). ATX was initially identified as an autocrine motility factor in human melanoma cells, and it is endogenously expressed in multiple tissues such as the ovary, intestine, kidney, prostate, testis, colon and lung (7, 8, 9). Proper regulation

of the expression and activity of ATX was found to play an essential role in embryogenesis by regulating vasculature maturation and angiogenesis, and this activity was responsible for the correct concentration of LPA in plasma (10, 11, 12).

Signal transducer and activator of transcription 3 (STAT3) is a crucial regulator of gene expression in response to signalling of the glycoprotein 130 (gp130) family of cytokines that includes IL-6 (13). The STAT3 signalling pathway plays a key role in regulating growth, survival, differentiation and pathogen resistance (14). Constitutive activation of the STAT3 signalling pathway has been observed in several human cancers, including breast cancer, multiple myeloma, head and neck cancer, ovarian cancer and prostate cancer (15, 16, 17, 18). The activation/phosphorylation of STAT3 is dependent on certain cytokines (19). One of these cytokines, IL-6, is suspected of mediating malignant behaviours in various cancers, including breast cancer, renal cell carcinoma, gastric cancer and colorectal cancer, by enhancing the expression of angiogenesis-related genes such as VEGF (20, 21, 22, 23). ATX has been reported to be a target of STAT3 transcriptional regulation in breast cancer (24).

Recently, ATX was reported to play an important role in the development and progression of some tumour types (8). Elevated levels of ATX have been demonstrated to be positively associated with the aggressive behaviour of tumours including renal cell carcinoma (25), hepatocellular carcinoma (26), melanoma (11), ovarian cancer (27) and breast cancer (28). However, to the best of our knowledge, the potential role of ATX in promoting the progression of pNEN has not been reported. Therefore, in the present study, we aimed to explore the underlying mechanisms of ATX and its possible usefulness in improving treatment and determining the prognosis of pancreatic neuroendocrine neoplasms.

Materials and methods

Clinical samples

A total of 34 snap-frozen tumour tissues ($n=17$), paired normal adjacent pancreatic tissues ($n=17$) and paraffin-embedded tissues ($n=34$) from patients with pNENs were obtained from the Department of General Surgery, The Third Xiangya Hospital, Central South University (Changsha, China). The study was approved by The Third Xiangya Hospital Clinical Research Ethics Committee. Consent was obtained from each patient after full

explanation of the purpose and nature of all procedures used. Samples were stored at -80°C (frozen tissue) or room temperature (paraffin samples) for expression analysis by quantitative reverse transcriptase PCR, Western blot and/or immunohistochemistry. None of the patients had received radiotherapy or chemotherapy prior to surgery. The diagnosis of all pNEN patients was based on the results of pathological sections. Tumour grade was determined according to the World Health Organization (WHO) grading system (29).

Cell culture

The human metastatic, adherent pNEN cell line, BON1, was obtained from the American Type Culture Collection and grown as a monolayer in 75 cm² flasks (Corning, NY, USA) in a 1:1 mixture of RPMI 1640 and Ham's F-12 media supplemented with 10% foetal bovine serum, penicillin and streptomycin (100 IU/mL) at 37°C with 5% CO₂ (30). To investigate the role of interleukin-6 (IL-6) in the activation of STAT3, BON1 cells were treated with recombinant human IL-6 (25 ng mL⁻¹) (Cell Signaling Technology) for different periods (24 h, 48 h, 72 h). The period (72 h) at which IL-6 exerted its maximum effect on BON1 cells was chosen for study.

Protein extraction and Western blot analysis

Proteins from tissue (1×2 mm) or BON1 cells were extracted using RIPA buffer containing complete protease inhibitors (Sigma-Aldrich) according to the manufacturer's instructions, and the protein concentration was determined using a BCA Protein Determination Kit (Thermo Scientific) following the manufacturer's instructions. Western blots were processed as previously described (31) using the following antibodies: anti-IL-6, anti-total-STAT3, and anti-ATX (all from Abcam); and anti-phospho-STAT3 (Tyr705) (Cell Signaling Technology). A goat anti-rabbit secondary antibody was used (R&D Systems). Protein expression was quantified using ImageJ (NIH).

Immunohistochemistry

The expression of ATX was assessed on paraffin-embedded primary tumour samples by immunohistochemistry as previously described (32). Briefly, tissue sections were deparaffinised and rehydrated in a graded ethanol series. Heat-based antigen retrieval was carried out in citrate buffer. Tissue sections were then blocked with Universal Blocking Reagent (BioGenex, Fremont, CA, USA) and

incubated with anti-ATX antibody (Cell Signalling), before being washed and developed using goat anti-rabbit secondary antibody (Santa Cruz Biotechnology) and a DAB kit (Cell Signaling Technology). After the tissue sections were counterstained with haematoxylin and washed with water, they were incubated in graded alcohol solutions and mounted. Optical image capture and analysis were performed using a microscope (IX71; Olympus Corp.). The evaluation method of staining widely used by pathologists in pathological analysis was performed as previously described (33). Briefly, staining intensity was scored as 0 (no staining), 1 (light yellow), 2 (brown) or 3 (tan), for absent, weak, moderate or strong, respectively, and the staining percentage was given a score of 0 (absent) for <5% positive staining, 1 (focal) for 5–<50% positive staining or 2 (diffuse) for ≥50% positive staining. The sum of the intensity and distribution scores was then used to determine ATX immunoreactivity. A score of 1 or 0 was considered to be indicative of low expression, whereas higher scores were considered to indicate high expression. Two pathologists assessed the specimens independently according to double-blind method. Negative slides were processed in the absence of primary antibody.

RNA extraction and quantitative reverse transcriptase PCR (qRT-PCR)

Total RNA was extracted from fresh specimens using TRIzol reagent (Thermo Fisher Scientific) according to the manufacturer's instructions. cDNA was prepared using a Superscript III cDNA Synthesis kit (Takara Bio, Inc.) following the manufacturer's protocol. qRT-PCR was performed using the FastStart Essential DNA Green Master mix (Roche Diagnostics) with the following primer pairs: ATX 5'-CGTGAAGGCAAAGAGAACACG-3'/5'-AAAAGTGGCATCAAATACAGG-3' and GAPDH 5'-ATGTTCTGTCATGGGTGTGAA-3'/5'-GTCTTCTGGTGCCAGTGAT-3'.

Quantitative PCR was performed in a 20 µL reaction solution containing 6 µL of nuclease-free water, 2 µL of cDNA template, 10 µL of Master Mix and 1 µL each of the forward and reverse primers. The amplification conditions were as follows: initial denaturation at 95°C for 15 min, followed by 45 cycles of denaturation at 95°C for 10s, annealing at 60°C for 30s and elongation at 72°C for 20s. The experiment was performed in triplicate. Qualitative PCR was also performed to confirm the presence of single, appropriately sized bands for each primer set. PCR data were analysed using the $\Delta\Delta C_T$ method as previously described (34).

ATX and STAT3 siRNA transfection

To specifically inhibit ATX and STAT3, siRNAs targeting these two proteins were used. The BON1 cells were cultured in 6-well plates (3.0×10^5 cells/well) for 72h prior to transfection. Subsequently, ATX siRNA (20 µmol/L; Thermo Fisher Scientific) and STAT3 siRNA (20 µmol/L; Thermo Fisher Scientific) were individually transfected into the BON1 cells. Negative control siRNA (20 µmol/L; Thermo Fisher Scientific) was used as a negative control in parallel. Transfections were performed with HiPerFect (Invitrogen) according to the manufacturer's protocol. Knockdown effectiveness was assessed by Western blot for total ATX and STAT3 levels.

Cell migration and invasion assay

A 24-well plate containing a 12-µm pore size polycarbonate membrane insert (Corning) coated with a uniform layer of dried basement membrane matrix solution (Corning) on the upper surface of the insert membrane was used for BON1 cell migration and invasion assays as previously described (35). Briefly, the lower compartment was filled with RPMI 1640/Ham's-F12 medium containing 30% FBS. After 48h of transfection, single-cell suspensions (3×10^5 cells/well in a volume of 300 µL) of BON1 cells were added to the upper chamber of each insert. After 48h of incubation at 37°C in a 5% CO₂ atmosphere, the inserts were removed, and cells on the upper surface of the insert membrane were removed with a cotton swab. The invaded cells were fixed and stained with 0.05% crystal violet. Membranes were excised. Cells that were able to invade or migrate (located on the bottom of the membrane) were counted with a microscope (IX71; Olympus Corp.) in nine individual fields per membrane.

Statistical analysis

Statistical analyses were performed using Prism 5 (GraphPad Software). Differences between two groups were estimated with Student's *t* test or Fisher's exact test as appropriate. Data were presented as the mean ± standard deviation. A *P* value <0.05 was considered statistically significant.

Results

ATX expression is upregulated in pNENs

The expression of ATX in pNEN and matched adjacent normal pancreatic tissue samples was detected by qRT-PCR and immunohistochemistry. As shown in

Fig. 1, the expression of ATX was significantly higher in pNEN tissues than that in the matched adjacent normal pancreatic tissues.

ATX expression levels are significantly correlated with tumour grade, lymph node metastasis and TNM stage

Our previous studies showed that ATX expression in pNEN tissues is significantly increased compared with that in matched adjacent normal pancreatic tissues. To investigate the associations between ATX expression and pNEN clinicopathologic characteristics, we performed immunohistochemistry to detect ATX expression in 34 paraffin-embedded pNEN tissues. The results revealed that 22 (64.7%) of 34 patients with pNEN exhibited

high ATX expression and that ATX expression was significantly lower in normal pancreatic tissues than in pNEN tissues. The relationships between ATX expression and clinicopathological pNEN features are shown in **Table 1**. Our results indicate that high ATX expression was positively correlated with tumour grade ($P=.029$), lymph node metastasis ($P=.013$) and TNM stage ($P=.012$).

ATX and STAT3 affect the invasion capacity of BON1 cells

To investigate the role of ATX in the development and progression of pNEN, BON1 cells were transfected with ATX or STAT3 siRNA, and the effects on cell invasion were investigated using a cell invasion assay (**Fig. 2**). The expression of ATX and STAT3 in BON1 cells transfected

with ATX and STAT3 siRNAs was significantly inhibited (Fig. 2A and B). The number of invaded BON1 cells on the bottom of the membrane was significantly reduced after transfection with ATX or STAT3 siRNA (Fig. 2C, D, E and F) compared with negative control transfection. These data indicated that ATX and STAT3 affected the invasion capacity of the BON1 cells.

ATX may be a direct target of STAT3

ATX was predicted to be a downstream target of STAT3 from genecard database (<http://www.genecards.org/>) by using bioinformatics tools including BLAST and PathCards (36). To test this hypothesis in pNEN, Western blot was used to detect the expression of ATX following the downregulation of STAT3 expression. As shown in Fig. 3, in BON1 cells, the siRNA-mediated downregulation of STAT3 caused a significant reduction in ATX protein expression. These findings indicated that ATX may be a direct target of STAT3.

IL-6 expression in human pNEN is associated with STAT3 pathway activation

It has been demonstrated that IL-6 impacts the metastatic behaviour of various tumours (37). We examined IL-6

expression and invasive signalling pathways in human pNEN tissues. By Western blot analysis, IL-6 expression was significantly higher in pNEN tissues than that in paired adjacent normal pancreatic tissues. Additionally, increased IL-6 levels were associated with increased phosphorylation of STAT3 (Fig. 4).

Impact of IL-6 on signalling pathways in BON1 cells

To examine the impact of IL-6 on signalling pathways in BON1 cells, we first determined STAT3 expression in IL-6-treated BON1 and control cells. IL-6 treatment led to robust STAT3 activation as reflected by increased STAT3 phosphorylation in IL-6-treated BON1 cells compared to control cells, which did not show any STAT3 phosphorylation (Fig. 5A, B and C). ATX expression was investigated and shown to be strongly upregulated in IL-6-treated BON1 cells (Fig. 5A and B).

Discussion

In the present study, we showed that ATX expression level was significantly upregulated in pNEN tissues compared with adjacent normal pancreatic tissues and that high ATX expression was positively correlated with tumour grade, lymph node metastasis and TNM stage. Additionally, the function of ATX in the pNEN cell line BON1 was investigated, and we found that ATX downregulation suppressed the invasive capacity of BON1 cells. In this study, we also showed that pNEN cell line BON1 upregulated ATX expression when stimulated by IL-6. Furthermore, STAT3 signalling was implicated as a critical effector pathway in response to IL-6 treatment. These *in vitro* observations were consistent with observations in human neuroendocrine disease, in which increased ATX expression and STAT3 phosphorylation were identified in pNEN tissues with elevated IL-6 expression levels.

The expression of ATX has been reported to be upregulated in many different types of cancer and to be associated with the oncogenesis and development of these cancers (8). Kishi *et al.* showed that the overexpression of ATX in glioblastoma contributed to the invasiveness of cancer cells by converting lysophosphatidylcholine to LPA (38). Yang *et al.* reported that ATX expression was closely linked to the invasiveness of breast cancer cells (39). The overexpression of ATX has also been demonstrated to be positively correlated with the migratory behaviour of thyroid carcinomas (40). Similar observations were identified in our studies, and in these pNENs, significant

Figure 2

The impact of ATX and STAT3 on the invasive capacity of BON1 cells. (A) Relative ATX expression levels in negative control and ATX siRNA-treated BON1 cells. (B) Relative STAT3 expression in negative control and STAT3 siRNA-treated BON1 cells. (C and D) Cell invasion assays (magnification, 400 $\times$). (C and E) Knockdown of ATX strongly decreased the invasive capability of BON1 cells compared with the negative control. (D and F) BON1 cells transfected with STAT3 siRNA exhibited decreased invasion compared with those transfected with the negative control. Experiments were performed thrice and representative images of invaded cells are shown. Data are presented as mean $\pm$ s.d. of three independent experiments. Student's *t* test was used for statistics analysis. **P* < 0.01 vs NC. ATX, autotaxin; NC, normal control; siRNA, small interfering RNA; STAT3, signal transducer and activator of transcription 3.

ATX expression was found only in cancerous tissue not in paired adjacent normal pancreas tissue. In this study, we also showed that high ATX expression was positively correlated with tumour stage, lymph node metastasis and tumour grade and that the downregulation of ATX suppressed the invasive capacity of BON1 cells, indicating that ATX might play a crucial role in the metastasis of pNEN.

It has been suggested that IL-6 expression is increased in the tumour microenvironment (41). IL-6 was found to contribute to the development and progression of various malignancies (20, 21, 37). Furthermore, the IL-6 signalling pathway, especially the IL-6/STAT3 signalling pathway, ultimately leads to transcriptional changes

that impact survival, proliferation, differentiation and migration (42). We examined the effects of IL-6 treatment on ATX expression and signalling pathways in BON1 cells and demonstrated that ATX expression was increased upon IL-6 exposure. The response of BON1 cells to IL-6 is most likely mediated by STAT3 activation, which has been reported to be associated with many tumours that have a poor prognosis, including bladder cancer (43). Our data showed that the effect of IL-6 on ATX upregulation in BON1 cells is likely mediated via STAT3 activation. It is unknown whether IL-6 is produced by pancreatic neuroendocrine tumour cells, but it has been reported that IL-6 was derived from intratumoral immune cells including tumour-associated macrophages (44).

Figure 3

(A and B) Transfection with ATX siRNA downregulated the protein expression of ATX in BON1 cells. (A and C) Transfection with STAT3 siRNA decreased the protein levels of STAT3 and ATX in BON1 cells. Experiments were performed thrice and blots are representative of one experiment. Data are presented as mean $\pm$ s.d. of three independent experiments. ATX, autotaxin; NC, normal control; siRNA, small interfering RNA; STAT3, signal transducer and activator of transcription 3.

To investigate the possible function of ATX and to reveal its underlying molecular mechanisms, the identification of regulatory targets is required. In this study of BON1 cells, the downregulation of STAT3 expression caused a reduction in the ATX protein level. This finding indicated that ATX may be a target of STAT3. STAT3 has previously been reported to be overexpressed and to be associated with malignant behaviours in numerous types of cancer (42). Additionally, STAT3 plays a crucial role in

the STAT3 signalling pathway, which has been shown to be involved in several cellular functions, including cell proliferation, survival and metastasis (42). Based on these results, ATX may be a target of STAT3. STAT3 may represent a drug target and STAT3 inhibitors may play a role in the treatment of pancreatic neuroendocrine neoplasms.

In conclusion, the present study has demonstrated that ATX expression is upregulated in pNEN tissues and is correlated with the metastatic capacity of pNEN cells,

Figure 4

Impact of IL-6 in pNENs. (A and B) Western blot analysis showing high IL-6 expression in pNEN tissues in comparison to normal control tissues. potentially via interaction with STAT3 activation. A better understanding of the mechanisms by which ATX regulates pNEN invasive capacity might help to design novel and more effective strategies for the treatment of this disease.
