## Abstract

*Objective:* Obesity is considered to be the strongest predictive factor for cardio-metabolic risk in women with polycystic ovary syndrome (PCOS). The aim of the study was to compare blood pressure (BP) in normal weight women with PCOS and controls matched for age and BMI.

*Methods:* From a Nordic cross-sectional base of 2,615 individuals of Nordic ethnicity, we studied a sub cohort of 793 normal weight women with BMI <25 kg/m<sup>2</sup> (512 women with PCOS according to Rotterdam criteria and 281 age and BMI-matched controls). Participants underwent measurement of BP and body composition (BMI, waist-hip ratio), lipid status, and fasting BG. Data were presented as median (quartiles).

*Results:* The median age for women with PCOS were 28 (25; 32) years, and median BMI was 22.2 (20.7; 23.4) kg/m<sup>2</sup>. Systolic BP was 118 (109; 128) mmHg in women with PCOS compared to 110 (105; 120) mmHg in controls and diastolic BP was 74 (67; 81) vs. 70 (64; 75) mmHg, both p<0.001. The prevalence of women with BP ≥140/90 mmHg was 11.1% (57/512) in women with PCOS vs. 1.8% (5/281) in controls, p<0.001. In women ≥ 35 years the prevalence of BP ≥140/90 mmHg was comparable in women with PCOS and controls (12.7% vs. 9.8%, p=0.6). Using multiple regression analyses, the strongest association with BP was found for age, waist circumference, and total cholesterol in women with PCOS.

*Conclusions:* Normal weight women with PCOS have higher BP than controls. BP and metabolic screening is relevant also in young normal weight women with PCOS.

Word count: 3340

## Introduction

Polycystic ovary syndrome (PCOS) is the most common endocrine disorder in women of reproductive age, with a prevalence of 10-20% when the Rotterdam criteria are used (1). The PCOS diagnosis is based on at least two out of three criteria: Clinical or biochemical hyperandrogenism (HA), chronic oligo-anovulation and polycystic ovaries, with exclusion of other etiologies (2).

Women with PCOS are characterized by abdominal obesity, insulin resistance, dyslipidemia, and increased risk of the metabolic syndrome, which could be associated with increased risk of cardiovascular disease (CVD) (3). The definition of the metabolic syndrome includes elevated blood pressure (BP) (3). It is estimated that more than 30% of women with PCOS have BP >130/85 mmHg (4) and also young women with PCOS have around three times increased risk of hypertension (HT) compared to controls (3, 5-7). In accordance, the recent international PCOS guideline recommends that BP should be measured by time of PCOS diagnosis, and thereafter annually in all women with PCOS (8).

The cardio-metabolic risk in PCOS could differ by PCOS phenotype, and especially the long-term cardio-metabolic risk in normal weight women with PCOS is unknown. In a Danish national register-based study including 19,199 women with PCOS (9), we recently reported that the prospective risk of developing type 2 diabetes was not increased in normal weight Danish women with PCOS compared to controls (10). This has been confirmed in other studies by our group (11, 12). However, the risk of CVD including HT was significantly increased in women with PCOS compared to controls also after adjusting for baseline BMI (5). Furthermore, 24% of women with PCOS in a local subset of the study cohort, who developed CVD, were lean by the time of PCOS diagnosis (5). These findings suggested that the risk of CVD including HT was attenuated but not normalized in normal weight women with PCOS. In contrast, two recent meta-analyses did not find increased risk of the metabolic

syndrome including HT in normal weight women with PCOS (7, 13). Whether BP is higher in normal weight women with PCOS compared to controls therefore awaits clarification.

Determinants of BP in women with PCOS have not been extensively studied. Obesity is considered most important for cardio-metabolic risk in women with PCOS (7, 14), but the importance of BMI and/or central obesity for vascular health in normal weight women with PCOS is undetermined. Testosterone levels could be an important modifier of vascular health in PCOS, but whether testosterone has a protective or unfavorable impact on the risk of CVD in PCOS is debated (7, 15). We are not aware of studies investigating associations between testosterone levels and BP in normal weight study populations of women with PCOS.

Furthermore, the international guidelines for PCOS recommend measurements of lipids and blood glucose in all women with PCOS (8). The importance of measuring these metabolic risk markers for vascular health in normal weight women with PCOS is debated (10, 11, 16). The aims of this study were 1) to investigate if normal weight women with PCOS have higher BP than controls and 2) to investigate possible determinants for BP in normal weight women with PCOS.

## Materials and methods

### Inclusion criteria:

Women diagnosed with PCOS from Denmark, Finland, Norway and Sweden and with available BP assessment were included in this study. All women fulfilled the Rotterdam criteria for PCOS (2) and were of Nordic origin. Data regarding lipid status, testosterone levels, and glucose tolerance in the whole study cohort has been published earlier (11, 16, 17). Here we present data from women  $\geq 20$  years of age and  $\text{BMI} \leq 25 \text{ kg/m}^2$ . Participants and controls were recruited from outpatient clinics, hospitals, advertisements in newspapers, hospital staff and medical students as previously described (11, 16, 17). The controls were

recruited from outpatient clinics, hospital staff, medical students or by advertisement.

Exclusion criteria:

Women with use of hormonal contraceptives in the past 2 months prior to enrollment, ongoing pregnancy, breastfeeding, or serious endocrine disease were not included in the study. Controls had no signs or symptoms of PCOS.

The study was approved by the Ethics committee region of Southern Denmark, Ethics committee of the Northern Ostrobothnia Hospital District, Regional committee for medical and health research ethics - Mid-Norway, Regional committee for medical and health research ethics – South-East Norway, Ethical review committee in Uppsala, Etikprövningsmyndigheten, Stockholm and Regionala etikprövningsnämnden in Gothenburg (11, 16, 17).

Consent has been obtained from each patient or subject after full explanation of the purpose and nature of all procedures used.

Study protocol:

All women with PCOS and controls underwent clinical examination: Measurement of height, weight, waist and hip circumference, Ferriman-Gallwey (FG)-score for hirsutism and transvaginal ultrasound. Clinical hyperandrogenism (hirsutism) was diagnosed when a woman had FG-score  $\geq 8$ .

BP was measured while supporting the upper limb, ensuring the cuff was at heart level, using a correct size of the cuff and not talking with the person during the process. The women avoided caffeine, smoking and exercise for at least 30 minutes before the measurement.

Protocols regarding measurement of BP varied between the seven different sites in the following manner:

Odense University Hospital: Patients had 10 minutes rest while sitting, before one measurement was recorded.

Oulu University Hospital: Patients had 15 minutes rest while sitting. BP was measured twice with 1-minute interval. The mean of the two measurements was recorded.

Oslo University Hospital: Patients had 15 minutes rest while sitting. BP was measured twice with two minutes interval and the lowest BP was recorded.

Norwegian University of Science and Technology: Patients had 10 minutes rest while sitting. BP was measured three times at least two minutes apart. The mean of the second and third BP measurement was used.

Karolinska Institutet-Department of Women's and Children's health: Patients had five minutes rest while sitting, before one measurement was recorded.

University of Gothenburg, Sahlgrenska University Hospital: Patients had five minutes rest in a supine position. BP was measured two times with five minutes interval, and the mean was recorded.

Uppsala University: Patients had 30 minutes rest while sitting. BP was measured three times with five minutes intervals and the mean was recorded.

## **Assays**

Metabolic variables (glucose, lipid profile) were assayed by means of the routine methods used in the laboratories of the different study centers (11). Plasma total cholesterol, high-density lipoprotein (HDL), cholesterol and triglyceride (TG) were analyzed by enzymatic colorimetric reactions (Modular P, Roche), and low-density lipoprotein (LDL) cholesterol was calculated using the Friedewald equation (18). According to the Nordic Reference Interval Project 2000, the reference ranges for the serum lipid levels were similar in all subpopulations of the study. Serum testosterone was measured by liquid chromatography–mass spectrometry (LC/MS), and SHBG was measured by chemiluminometric immunoassays as reported earlier (11, 17). In Danish women, serum testosterone was analyzed using a

specific radio-immunoassay after ether extraction (19). This method shows a close correlation with the determination of testosterone levels using mass spectrometry (19).

Free androgen index (FAI) was calculated by dividing total testosterone with SHBG and multiplying by 100.

## Statistics

The primary study outcome was BP. We aimed to compare differences in BP between normal weight women with PCOS vs. controls and determinants of BP in women with PCOS. Given the inconsistency of previous study findings in lean women with PCOS, we did not perform a power calculation. We wanted to study two comparable groups with respect to age and BMI distribution in the patient and control groups. Hence, 512 women with PCOS were matched individually with one woman in the control group ( $n = 281$ ) according to age (age range 20–57 years), and BMI (range 18.8 - 24.8 kg/m<sup>2</sup> in the PCOS group and 18.7 - 24.7 kg/m<sup>2</sup> in the control group, 2.5-97.5 percentile interval). Matching was performed according to the nearest year of birth and BMI unit.

Epidemiological studies have evaluated the association of SBP, DBP, pulse pressure, mean BP and mid/BP with CVD outcomes. Among these, SBP and DBP are consistently best associated with CVD risk and are prioritized in this study (20, 21). BP 140/90 was used as threshold BP according to the European guidelines (22). Data are presented as median (quartiles) and  $n$  (%). Differences between women with PCOS and controls were evaluated by Mann-Whitney test (continuous variables) and Chi-square test. Country of inclusion was taken into account by entering country code as an independent variable (1: Denmark, 2: Finland, 3: Norway, 4: Sweden). In these analyses, we entered clinical relevant study outcome (BP, age, etc) as the dependent variable and country code and patient/controls as independent variables.

Several of the biochemical markers exhibited some deviation from a Gaussian distribution and we examined bivariate association between DBP, SBP, clinical and biochemical characteristics in women with PCOS and in controls separately by non-parametric Spearman correlation (r-values and P-levels).

Multiple linear regression analysis was used to examine the effect of lipid status, glucose status, and testosterone on SBP and DBP respectively, in women with PCOS. Variables included in the regression analyses were selected based on closest association with SBP and DBP respectively, based on results from bivariate correlation analyzes. The clinical setting differed at the study centers, and country code was entered as an independent variable in regression analyses. All models were corrected for age, waist circumference, and country of study inclusion (1: Denmark, 2: Finland, 3: Norway, 4: Sweden). Data were presented as  $\beta$ -coefficients (95% CI) and adjusted  $R^2$  values. In all regression models, model assumptions were validated through comprehensive residual analyses, as well as inspection of linearity and homogeneity of variance, and multicollinearity was assessed through variance inflation factors.

IBM SPSS statistics 25 statistical package was used. A P-value  $<0.05$  was considered significant.

## Results

Clinical and biochemical characteristics of women with PCOS and age- and weight-matched controls are presented in Table I. The number of patients included from Denmark was  $n=175$  (one study center), Sweden  $n=102$  (three study centers), Norway  $n=85$  (two study centers), and Finland  $n=149$  (one study center).

SBP and DBP were significantly higher in women with PCOS compared to controls.

Total testosterone, FAI and HbA1c were higher, and SHBG levels were lower in women with

PCOS vs. controls, whereas waist circumference, WHR, lipid status and fasting BG were comparable in the two study cohorts. All results, except HbA1c, remained significant after adjusting for country of study inclusion (Table 1).

The prevalence of BP  $\geq 140/90$  mmHg in different age groups in women with PCOS and controls is shown in Table II. BP  $\geq 140/90$  mmHg was observed in 11.1% (57/512) women with PCOS compared to 1.8% (5/281) controls. Furthermore, both SBP  $\geq 140$  mmHg (8.2% PCOS vs. 1.7% controls) and DBP  $\geq 90$  mmHg (7.4% PCOS vs. 0.3% controls) were higher than in controls. In women  $< 35$  years, the prevalence of BP  $\geq 140/90$  mmHg was 10.9% (47/433) in women with PCOS compared to 0% (0/230) in controls,  $p < 0.001$ . In women  $\geq 35$  years the prevalence of BP  $\geq 140/90$  mmHg was 12.7% (10/79) in women with PCOS compared to 9.8% (5/51) in controls,  $p = 0.62$ .

Characteristics in women with PCOS according to BP  $<$  or  $\geq 140/90$  mmHg are shown in Table III. Women with BP  $\geq 140/90$  mmHg had higher waist circumference, WHR, FAI, total cholesterol, fasting BG and lower rate of anovulation and polycystic ovaries compared to women with BP  $< 140/90$  mmHg.

Bivariate associations with BP are shown in Table IV. In women with PCOS, SBP and DBP were positively correlated with BMI, waist circumference, WHR, total testosterone, lipid status (total cholesterol, TG, LDL), and fasting BG. The highest r-values were found for WHR, lipid status and fasting BG. In controls, the highest r-values were found in associations between BP and age, BMI, waist circumference and WHR.

Multiple regression analyses in women with PCOS are shown in Table V-VI.

SBP: Age and waist were significant predictors of SBP in the crude model. In adjusted analyses, the best individual marker of SBP was age and cholesterol. The  $R^2$  value of the fully adjusted model was 0.39.

DBP: Waist circumference and age was significantly associated with DBP in the crude model.

In adjusted analyses, the best individual marker of DBP was cholesterol. The  $R^2$  value of the fully adjusted model was 0.39.

## Discussion

In the present study, BP was significantly higher in young, normal weight women with PCOS compared to controls. In women with PCOS, higher BP was associated with greater waist circumference and unfavorable cholesterol, which supported the importance of metabolic screening. Testosterone levels were not associated with BP in women with PCOS.

Our finding of higher BP in normal weight Scandinavian women with PCOS is supported by recent studies. Ollila *et al.* (6) studied PCOS as an independent risk factor for HT in normal weight women with self-reported PCOS (n=100) in a population based cross-sectional study from the Northern Finland Birth Cohort. Ollila found that women with self-reported PCOS displayed higher BP by the age of 31 compared to controls (mean (SD) SBP 120 (13) vs. 117 (11) mmHg,  $p = 0.017$  and DBP 76 (10) vs. 72 (10) mmHg,  $p = 0.003$ ) (6). Moreover, PCOS was associated with HT and increased cardiovascular morbidity independent of BMI (6).

Pinola *et al.* found that overweight and obese Scandinavian women with PCOS (mean BMI 29 kg/m<sup>2</sup>) had 5 mmHg higher SBP and 4 mmHg higher DBP compared to controls, which was present already from <30 years of age (17). Higher BP in women with PCOS remained significant after adjustment for BMI and age (17). Recently, we performed a national register based study in a Danish cohort of 18,112 women with PCOS and 52,769 controls where the main study outcome was CVD events including HT and dyslipidemia (5). Included women had average age of 29 years and median follow up of 11.1 years (5). The odds ratio for development of CVD including HT and dyslipidemia was 1.7 in PCOS and the risk of HT was dependent on baseline metabolic risk profile (SBP and DBP, BMI, waist and triglycerides) (5). A total of 24% of women with PCOS and CVD were normal weight at the time of PCOS diagnosis (5). Holte *et al* applied 24h BP measurements and found significantly higher day-time systolic BP in Swedish women with PCOS (mean BMI 26 kg/m<sup>2</sup>), which persisted after adjusting for BMI, body fat distribution and insulin resistance (23). In

populations of other ethnic background than Nordic, Zachurzok-Buczynska *et al* reported higher 24-hour BP and higher day and night mean arterial BP in normal weight Polish women with PCOS compared to controls (24) and Bahri Khomami *et al* found higher SBP in Iranian women with PCOS (mean BMI 26 kg/m<sup>2</sup>) compared to controls (25). Joham *et al* conducted a cross sectional study in 8612 Australian women (500 women with PCOS, average BMI 28 kg/m<sup>2</sup>) and found higher risk of HT in normal weight women with PCOS vs. controls (26). In regression analyses, there was a trend towards an association between PCOS and HT (odds ratio: 1.6, 95% CI: 0.9–2.6,  $P = 0.09$ ), yet this did not reach significance (26). In contrast, other studies reported comparable BP in normal weight women with PCOS (originating from China (27) and Spain (28)) compared to controls. A recent meta-analysis found no difference in HT in non-obese women with and without PCOS (13). The number of participants included in the meta-analysis was limited, which resulted in a very wide confidence interval for the odds ratio of HT in normal weight women with PCOS compared to controls 2.44 (0.80; 7.43),  $p = 0.11$  (13). Among BMI-matched studies, Lim *et al.* performed subgroup analyses according to geographic region and found a significantly increased risk of metabolic syndrome in normal weight women with PCOS from Europe, but not from other regions (7). Furthermore, the greatest increase in prevalence of metabolic syndrome in women with PCOS compared to controls was in American study populations, which the authors suggested was likely to be related to obesity (7). Whether the metabolic risk profile in European women with PCOS differs from women with PCOS originating from other continents remains to be determined.

BP increased with age in the present study. Interestingly, the prevalence of BP > 140/90 mmHg was different between women with PCOS and controls. No control women with BMI < 25 kg/m<sup>2</sup> and age < 35 years had BP  $\geq$  140/90 mmHg, while the corresponding prevalence in women with PCOS was 10.9%. This finding supported that young normal-weight women

with PCOS need attention regarding BP measurement. The absolute level of SBP and DBP was not remarkably high. In European guidelines, BP lowering drug treatment is recommended with office BP  $\geq 140/90$  mmHg and  $> 5\%$  fatal CVD risk (22). However, previous studies reported that the risk for CVD increases in a log-linear fashion already from SBP levels  $< 115$  mmHg to  $> 180$  mmHg, and from DBP levels  $< 75$  mmHg to  $> 105$  mmHg (29, 30). These risk gradients were homogenous across subgroups of sex and ethnicity (29). Waist circumference and lipid status were the most important determinants of BP in our normal weight study cohort of women with PCOS. These findings were in accordance with studies in populations without PCOS that showed a close relation between BMI and BP with no evidence of a threshold for BMI (31). Furthermore, for cholesterol levels in the range 5.2-11.6 mmol/l, each 1 mmol/L increase was associated with 7% higher mortality (32). Recent findings suggested that young individuals are more affected by higher lipid levels than older individuals. In the age groups of 18–34, 35–44, 45–54, 55–64, 65–74, and 75–99 years, each 1 mmol/L higher level for total cholesterol  $\geq 5.2$  mmol/l, increased mortality by 14%, 13%, 8%, 7%, 6%, and 3%, respectively (32). HbA1c and blood glucose is associated with all-cause mortality also in individuals without T2D (33, 34), and the association between glucose and mortality is closer at younger ages (35). Our findings suggest that the same metabolic risk markers are relevant in women with PCOS as in other study populations. Our results demonstrate that waist circumference and lipid status have the highest impact on SBP, supporting the hypothesis that lifestyle intervention is important also in young and normal weight women with PCOS. Furthermore, intervention against metabolic risk could be of special relevance in young study cohorts, especially if BP is increased (16). We did not standardize insulin measurement across counties, and therefore, these data were not included in the present manuscript. Insulin resistance could be a mediator of metabolic risk in women with PCOS (36) and this hypothesis should be further evaluated in future studies. Obstructive

sleep apnea is associated with higher risk of metabolic disease including HT (37). The risk of obstructive sleep apnea in normal weight women with PCOS and HT should be further investigated in future studies.

Testosterone showed a positive association with BP in bivariate analyses. In regression analyses, however, the impact of testosterone on BP was not significant. These results could be explained by an interaction between higher testosterone, central obesity and metabolic risk, which is also observed in obese women with PCOS (4). In accordance, Pinola et al (17) found that higher BP in women with PCOS was not related to whether the women were normo- or hyperandrogenic. Androgen levels decline in ageing women with PCOS (38, 39) and the impact of testosterone on BP in ageing women with PCOS could decline compared to metabolic risk factors such as central obesity, lipid status and blood glucose levels.

Strengths and limitations apply to the present study. We included a large and well-characterized study population of homogenous ethnicity, which was a major strength of the study. However, the study cohort included women referred to outpatient clinics, which could imply a more severe PCOS phenotype. The women participating in the present study were included in other publications from the author group (11, 16, 17), which could infer study bias. We only allowed gold standard steroid measurements in the present study (mass spectrometry or ether extraction followed by radio-immuno assay), but differences in applied steroid analyses between study centers could have affected study results. In regression analyses, we corrected for country of diagnosis, but we have been cautious regarding conclusions including results from these measurements.

A major limitation of this study was that seven different study centers were involved, which implied different methods of BP measurement and in most cases only one office BP measurement was performed. The applied methods in all centers resembled methods for

measuring BP in a daily clinic, which may represent a study strength. However, it is important to recognize that diagnosis and classification of elevated BP should be based on  $\geq 2$  readings obtained on  $\geq 2$  occasions in order not to overestimate the prevalence of HT (20). BP measurements were obtained in a similar way in women with PCOS and controls and the limitation of only one BP measurement did not affect the observed differences between the study cohorts. However, the current study design does not allow us to draw conclusions on the prevalence of diagnosis of HT and indication for medical treatment for HT in the study cohort. Furthermore, the study should be repeated in populations of other ethnic background.

Taken together, we found that young and normal weight women with PCOS had higher BP compared to age and BMI matched controls. In women with PCOS, BP was positively associated with waist and lipid status, which underlined the importance of metabolic screening also in young and normal weight women with PCOS.
